USB ATTACKS

Small devices, big threats

USBs can carry malware that puts your data and system control at risk.

Some tampered USBs can compromise sensitive data by intercepting and manipulating information between your device and the computer.

Beware of USB sticks intentionally left in public places – they may contain malicious software!

Some USB drives run malicious software automatically when connected, without user action.

Connecting any USB without knowing its origin can result in serious security compromises to your device and personal data.
